The ability to engineer ordered arrays of objects on multiple length AB scales has potential for applications such as microelectronics, sensors, waveguides, and photonic lattices with tunable band gaps. Since the invention of surfactant templated mesoporous sieves in 1992, great progress has been made in controlling different mesophases in the form of powders, particles, fibers, and films. To date, although there have been several reports of patterned mesostructures, materials prepd. have been limited to metal oxides with no specific functionality. For many of the envisioned applications of hierarchical materials in microsystems, sensors, waveguides, photonics, and electronics, it is necessary to define both form and function on several length scales. In addn., the patterning strategies utilized so far require hours or even days for completion. Such slow processes are inherently difficult to implement in com. environments. We present a series of new methods of producing patterns within seconds. Combining sol-gel chem., Evapn.-Induced Self-Assembly (EISA), and rapid prototyping techniques like pen lithog., ink-jet printing, and dip-coating on micro-contact printed substrates, we form hierarchically organized silica structures that exhibit order and function on multiple scales: on the mol. scale, functional org. moieties are positioned on pore surfaces, on the mesoscale, mono-sized pores are organized into 1-, 2-, or 3-dimensional networks, providing size-selective accessibility from the gas or liq. phase, and on the macroscale,
